APPLICATION FOR LETTERS PATENT

**Renaming of Virtual Communication Port for IR
Devices**

Inventor(s):
Kent D. Cedola

ATTORNEY'S DOCKET NO. MS1-403USC

1 **TECHNICAL FIELD**

2 This invention relates to computer operating systems, and particularly, to
3 computer methods for identifying and naming communication ports associated
4 with infrared (IR) devices.

5

6 **BACKGROUND**

7 Conventional computers have multiple communication ports (or "COMM"
8 ports) for connecting peripheral devices, such as printers or modems. One of the
9 ports is typically dedicated to communicate with infrared (IR) devices via an IR
10 transceiver. Common IR devices include handheld computers (e.g., palmtops,
11 pocket computers, personal digital assistants, personal organizers, etc.), keyboards,
12 a computer mouse, remote control handset, and the like. The computer is typically
13 equipped with an IR receiver, which is mounted as part of the unit or externally
14 (e.g., an IR dongle). The IR receiver is connected to the dedicated COMM port.

15 One problem that arises is when a user first tries to configure his/her
16 computer for communication with the IR device. In a Windows-brand operating
17 system from Microsoft Corporation, the communication ports are represented by
18 virtual port names, such as "COM0", "COM1",..., "COM9", and so on. During
19 configuration, the user is presented with a list of these virtual port names.
20 Unfortunately, the user is required to know, or guess, which communication port is
21 associated with IR devices. For instance, it may be that COM4 is the port for IR
22 devices, but such information would not be readily apparent or obvious to the user.
23 The user can obtain the name of the IR virtual COMM port from the Control
24 Panel.Wireless dialog, but this is not obvious for most user.

1 Accordingly, there is a need to improve the user experience during
2 configuration of a computer for IR communication.

3

4 **SUMMARY**

5 This invention concerns an operating system and method for identifying and
6 naming communication (COMM) ports associated with infrared (IR) devices.
7 According to a described implementation, the system detects all available COMM
8 ports, identifies the COMM port dedicated to an IR transceiver that interfaces with
9 IR devices, and renames that COMM port from a non-descriptive virtual port name
10 (e.g., “COM4”) to another, more descriptive virtual port name (e.g., “Infrared
11 Port”). The descriptive virtual port name is then used when presenting a list of
12 available COMM ports to a user. In this manner, rather than seeing a list of
13 indistinguishable virtual port names (e.g., “COM0”, “COM1”, … “COM9”) in
14 which one may be dedicated to the IR transceiver, the user is presented with a list
15 of virtual port names that includes one conspicuously descriptive port name (e.g.,
16 “Infrared Port”). This removes the guesswork and frustration for the user during
17 configuration. The system also enables reverse conversion from the descriptive
18 name back to the non-descriptive virtual port name for internal use.

19

20

21 **BRIEF DESCRIPTION OF THE DRAWINGS**

22 The same reference numbers are used throughout the drawings to reference
23 like components and features.

24 Fig. 1 is a block diagram of a computer coupled to an IR device.

1 Fig. 2 is a flow diagram of a method for identifying a COMM port
2 dedicated to an IR transceiver used to communicate with IR devices and renaming
3 the COMM port with a user-friendlier, descriptive virtual port name.

4 Fig. 3 is a diagrammatic illustration of a graphical user interface window
5 embodied as a “COMM Port” dialog box.

6 Fig. 4 is a flow diagram of a method for detecting the available COMM
7 ports, which is used in the Fig. 2 method.

8 Fig. 5 is a flow diagram of a method for converting the descriptive virtual
9 port name back to the original virtual port name.

10

DETAILED DESCRIPTION

11 Fig. 1 shows a computer system 20 having a host computer 22 connected to
12 communicate with an infrared (IR) device 24 via a wireless IR connection 26. The
13 host computer 22 may be embodied in many ways including, for example, a
14 desktop computer, a laptop computer, a set-top box, or the like. The IR device 24
15 may also be implemented in a number of ways, such as a handheld computer, a
16 telephone or other communication device, a personal digital assistant, and so forth.
17 The IR device may also be configured to run an operating system (not shown),
18 such as the Windows CE operating system from Microsoft Corporation.

19
20 The host computer 22 has a memory 30, processor 32, a display 34, and one
21 or more input devices 36 (e.g., keyboard, mouse, etc.). The memory 30 generally
22 includes both volatile memory (e.g., RAM) and non-volatile memory (e.g., Flash,
23 ROM, hard disk, etc.). The compute 22 is also equipped with multiple
24 communication (COMM) ports 38 and an infrared (IR) transceiver 40 to

1 communicate with the IR device 24. The IR transceiver 40 is connected to one of
2 the COMM ports 38 and may reside internally or externally.

3 An operating system 50 resides in memory 30 and executes on the processor
4 32. The computer 22 preferably runs a Windows-brand operating system from
5 Microsoft Corporation, such as Win32-based products (e.g., Windows 95,
6 Windows 98, etc.), although other operating systems may be used. One or more
7 application programs 52 are loaded into memory 30 and run on the operating
8 system 50. Examples of applications 52 include email programs, scheduling
9 programs, remote device services programs, word processing programs, Internet
10 browser programs, and so on.

11 The operating system 50 has a user interface (UI) 60, which preferably
12 supports a graphical windowing environment. The operating system 50 also has a
13 set of software drivers 62 for various hardware components, including any
14 peripheral devices connected through the COMM ports. An IR driver is provided
15 in the set of drivers 62 to manage the COMM port dedicated to the IR transceiver
16 40.

17 A system registry 64 is provided in the operating system 50 to track
18 configuration parameters of the computer 22, including whether the IR transceiver
19 40 is configured for operation with the computer 22. Among other things, the
20 registry 64 keeps track of the COMM ports 38 and the virtual port names
21 associated with the COMM ports. In Win32 products, the virtual port names
22 follow the format “COM#”, where the “#” is a numeric value. For instance, it is
23 common to have a number of ports with associated virtual port names of “COM0”,
24 “COM1”, ... “COM9”.

1 The computer 22 has a port detector 66 and a port renaming module 68,
2 which are shown implemented as part of the operating system 50, but may be
3 implemented separately. The port detector 66 detects which COMM ports are
4 available and returns a list of the available ports. From this list, the port renaming
5 module 68 identifies which COMM port is specially dedicated to IR transceivers
6 and renames the COMM port from a non-descriptive virtual port name (e.g.,
7 “COM4”) to another, more descriptive virtual port name (e.g., “Infrared Port”). In
8 this manner, the system 20 offers an improved user experience during
9 configuration of the computer 22 for IR communication with the IR device 24.
10 Rather than seeing a list of indistinguishable virtual port names (e.g., “COM0”,
11 “COM1”, … “COM9”) in which one may be dedicated to communication with IR
12 devices, the user is presented with a list of virtual port names that includes one
13 conspicuously descriptive port name, such as “Infrared Port”. This removes the
14 guesswork, confusion, and any frustration on the part of the user during
15 configuration.

16 Fig. 2 shows a method for identifying a COMM port dedicated to
17 communicate with IR devices and renaming the COMM port with a user-friendlier,
18 descriptive virtual port name. These steps are performed, for example, in software
19 by the port detector 66 and the port renaming module 68. At step 100, the port
20 detector 66 generates a list of available communication ports. One preferred
21 technique for generating this list at step 100 is described below in more detail with
22 respect to Fig. 3.

23 For purposes of discussion, suppose that the port detector 66 generates a list
24 of seven available communication ports: COM0, COM1, COM3, COM4, COM6,
25 COM7, and COM9. At this point, the list is kept hidden and is not presented to the

1 user. Rather, the port renaming module 68 will first utilize the list to evaluate
2 whether any of these COMM ports is dedicated to the IR transceiver 40.

3 At step 102, the port renaming module 68 determines whether the COMM
4 port for communicating with an IR device is available. In one implementation, the
5 port renaming module 68 checks the system registry 64 to determine whether an IR
6 transceiver 40 has been configured for the computer system and which, if any, of
7 the available COMM ports is associated with the IR transceiver 40. If no IR
8 transceiver is listed in the registry 64 (i.e., the “no” branch from step 102), the
9 computer displays the list of non-descriptive virtual port names for the available
10 COMM ports (step 108). In this case, there is no need for renaming a port because
11 there is no IR transceiver registered.

12 On the other hand, suppose that the port renaming module 68 learns from
13 the registry 64 that IR transceiver 40 is registered and a communication port (e.g.,
14 “COM4”) is associated with it. In this case (i.e., the “yes” branch from step 102),
15 the port renaming module 68 retrieves the virtual port name “COM4” from the
16 registry 64 (step 104). The port renaming module 68 then replaces the non-
17 descriptive virtual port name “COM4” with a more descriptive and IR-related
18 virtual port name, such as “Infrared Port” (step 106). After the renaming, the
19 computer 22 displays the list of non-descriptive virtual port names for available
20 COMM ports, along with a descriptive virtual port name for the IR-dedicated port
21 (step 108). Table 1 summarizes this process.

1 **Table 1**

2 Virtual Port Names of Available 3 COMM ports (after Step 102; 4 Not Displayed to User)	5 Renamed Virtual Port Names 6 (after Step 106; Displayed to 7 User)
8 COM0	9 COM0
9 COM1	10 COM1
10 COM3	11 COM3
11 COM4	12 Infrared Port
12 COM6	13 COM6
13 COM7	14 COM7
14 COM9	15 COM9

11 Fig. 3 shows an exemplary dialog box 120 that lists the virtual port names
12 for the user. Notice that the virtual port name “COM4” is renamed “Infrared Port”
13 (or other suitable name). With this list, the user easily understands which COMM
14 port is associated with the IR device, thereby improving the user experience during
15 configuration.

16 Fig. 4 shows one preferred method for detecting the available COMM ports
17 at step 100 in Fig. 2. These steps are performed, for example, in software by port
18 detector 66. At step 200, the port detector 66 clears a table of COMM ports. It
19 then sets the current COMM port name to an initial virtual port name, such as
20 “COM0” (step 202). At step 204, the port detector 66 attempts to open the current
21 COMM port name. In the case of a Windows-brand operating system, the port
22 detector 66 uses the CreateFile Win32 API (application program interface) to open
23 each possible COMM port name. A Win32 result code of “NOERROR” or
24 “ERROR_ACCESS_DENIED” indicates that the communication port is present.
25

1 The “NOERROR” code implies that the port is present and unused. The
2 “ERROR_ACCESS_DENIED” code implies that the port is present, but presently
3 busy.

4 If the COMM port is found (i.e., the “yes” branch from step 206), the port
5 detector 66 adds the current virtual COMM port name (e.g., “COM0”) to the table
6 (step 208) and increments the current COMM port name to the next value, such as
7 “COM1” (step 210). If, on the other hand, the COMM port is not found (i.e., the
8 “no” branch from step 206), the port detector 66 does not add the current COMM
9 port name to the table and increments to the next COMM port name (e.g.,
10 “COM1”).

11 The port detector 66 repeats this process until it has cycled through all of
12 the port names, as indicated by decision step 212 and loop back to step 204. Once
13 the port detector has attempted to open all of the COMM ports, it returns the table
14 containing the detected COMM ports (step 214).

15 Fig. 5 shows a method for converting the descriptive virtual port name (e.g.,
16 “Infrared Port”) back to the original virtual port name (e.g., “COM4”). This
17 process is useful, for example, in the case where the user enters a friendly and
18 descriptive name, such as “Infrared Port”, during configuration and the computer
19 internally prefers handling its own non-descriptive virtual port name, such as
20 “COM4”. These steps are preformed in software by the port renaming module 68.

21 At step 300, the port renaming module 68 determines whether the COMM
22 port name is currently set to a descriptive port name, such as “Infrared Port”. If
23 not (i.e., the “no” branch from step 300), it simply returns the present port name
24 (step 306). On the other hand, if a descriptive port name exists (i.e., the “yes”
25 branch from step 300), the port renaming module 68 retrieves the virtual port name

1 “COM4” from the registry 64 (step 302). The port renaming module 68 then
2 substitutes the non-descriptive virtual port name “COM4” for the descriptive
3 virtual port name “Infrared Port” (step 304). After the renaming, the port
4 renaming module 66 returns the virtual port name for internal use (step 306).

5 Although the invention has been described in language specific to structural
6 features and/or methodological steps, it is to be understood that the invention
7 defined in the appended claims is not necessarily limited to the specific features or
8 steps described. Rather, the specific features and steps are disclosed as preferred
9 forms of implementing the claimed invention.
